Introduction

Whiplash is defined as a sudden *extension* of the cervical spine (backward movement of the neck) and *flexion* (forward movement of the neck). This type of trauma is also referred to as a *cervical acceleration-deceleration* (CAD) injury. Rear-end or side-impact motor vehicle collisions are the number one cause of whiplash with injury to the muscles, ligaments, tendons, joints, and discs of the cervical spine.

This guide will help you understand

- what parts make up the spine and neck
- what causes this condition
- how doctors diagnose this condition
- what treatment options are available

Anatomy

What parts make up the **spine and neck**?

The human spine is made up of 24 spinal bones, called *vertebrae*. Vertebrae are stacked on top of one another to form the spinal column. The spinal column is the body's main upright support.

The *cervical spine* is formed by the first seven vertebrae referred to as C1 to C7. The cervical spine starts where the top vertebra (C1) connects to the bottom edge of the skull.

©MMG 2000

The cervical spine curves slightly inward and ends where C7 joins the top of the *thoracic spine*. This is where the chest begins.

©MMG 2002

A bony ring attaches to the back of the vertebral body. When the vertebrae are stacked on top of each other, the rings form a hollow tube. This bony tube surrounds the spinal cord as it passes through the spine. Just as the skull

©MMG 2006

protects the brain, the bones of the spinal column protect the spinal cord.

As the spinal cord travels from the brain down through the spine, it sends out nerve branches between each vertebrae called *nerve roots*. The nerve roots that come out of the cervical spine form the nerves that go to the arms and hands.

Two spinal nerves exit the sides of each spinal segment, one on the left and one on the right. As the nerves leave the spinal cord, they pass through a small bony tunnel on each side of the vertebra, called a *neural foramen*. (The term used to describe more than one opening is *neural foramina*.)

Each spinal segment includes two vertebrae separated by an *intervertebral disc*, the nerves that leave the spinal cord at that level, and the small facet joints that link each level of the spinal column.

An intervertebral disc is made of *connective tissue*. Connective tissue is the material that holds the living cells of the body together. The disc is a specialized connective tissue structure that separates the two vertebral bodies of the spinal segment. The disc normally works like a shock absorber. It protects the spine against the daily pull of gravity. It also protects the spine during activities that put strong force on the spine, such as jumping, running, and lifting.

An intervertebral disc is made up of **two parts**. The center, called the *nucleus*, is spongy. It provides most of the ability to absorb shock. The nucleus is held in place by the *annulus*, a series of strong ligament rings surrounding it. *Ligaments* are strong connective tissues that attach bones to other bones.

Causes

What causes this condition?

When the head and neck are suddenly and forcefully whipped forward and back, mechanical forces place excessive stress on the cervical spine. Traumatic disc rupture and soft tissue damage can occur. The cartilage between the disc and the vertebral bone is often cracked. This is known as a *rim lesion*.

Damage to the disc can put pressure on the nerves as they exit the spine. The pressure or irritation can be felt as numbness on the skin, weakness in the muscles, or pain along the path of the nerve. Most people think of these symptoms as indications of a pinched nerve. Health care providers call this condition *cervical radiculopathy*.

Soft tissue around the facet joint can be injured. Many of the pain-sensing nerves of the spine are in the facet joints. The normally smooth surfaces on which these joints glide can become rough, irritated, and inflamed. Studies show that neck pain often comes from the damaged facet joints.

Low back pain is a common feature after a whiplash injury. Studies show that there is significant electrical activity in the muscles of

the lumbar spine when the neck is extended. This effect increases when there is neck pain, possibly as a way to help stabilize the spine when neck pain causes weakness.

More than anyplace else in the body, the muscles of the neck sense sudden changes in tension and respond quickly. Tiny spindles in the muscles signal the need for more muscle tension to hold against the sudden shift in position.

The result is often muscle spasm as a self-protective measure. The increased muscle tone prevents motion of the inflamed joint. You may experience neck stiffness as a result.

Risk Factors

Each year, about three million people experience whiplash injuries to their neck and back. Of these three million people, only about one-half, will fully recover. About 600,000 of those individuals will have long-term symptoms, and 150,000 will actually become disabled as a result of the injury.

There are many factors that come into play when a person is injured in a rear-end motor vehicle accident. Any one or more of the following factors can affect recovery:

- Head turned one way or the other at the time of the impact (increases risk of nerve involvement with pain down the arm)
- Getting hit from behind (rear-impact collision)
- Previous neck pain or headaches

- Previous similar injury
- Being unaware of the impending impact
- Poor posture at the time of impact (head, neck, or chest bent forward)
- Poor position of the headrest or no headrest
- Crash speed under 10 mph
- Being in the front seat as opposed to sitting in the back seat of the car
- Collision with a vehicle larger than yours
- Being of slight build
- Wearing a seatbelt (a seat belt should always be worn, but at lower speeds, a lap and shoulder type seat belt will increase the chances of injury)

Symptoms

What are some of the symptoms of whiplash?

- Neck pain or neck pain that travels down the arm (radiculopathy)
- Headaches
- Low back pain (LBP)
- Jaw pain
- Dizziness

Ninety percent of patients involved in whiplash type accidents complain of neck pain. This is by far the most common symptom. The pain often spreads into the upper back, between the shoulder blades, or down the arm. Neck pain that goes down the arm is called *radiculopathy*.

Low back pain (LBP) can occur as a result of a whiplash injury. The Insurance Research Council reports that LBP occurs in 39 per cent of whiplash patients. Some studies found LBP to be present in 57 per cent of rear-impact collisions in which injuries were reported and 71 per cent of side-impact collisions.

Jaw pain as a result of *temporomandibular joint* (TMJ) injury can also cause painful headaches. The TMJ is formed by the bone of the *mandible* (lower jaw) connecting to the temporal bone at the side of the skull. The TMJ is a hinge joint that allows the jaw to open and close and to move forward, back, and sideways. Pain in this joint is called *temporomandibular joint disorder* (TMD).

Dizziness is quite common with a sense of lost balance being reported. It is caused by an injury to the joints of the neck called *facet* or *zygapophyseal* joints. When dizziness is reported, it should be distinguished from vertigo (also known as benign *paroxysmal positional vertigo* (BPPV), which results from an injury to the inner ear.

Other symptoms often reported include, but are not limited to: shoulder pain; numbness or tingling in the arms, hands, legs or feet; facial pain, fatigue, confusion, poor concentration, irritability, difficulty sleeping, forgetfulness, visual problems, and mood disorders.

It is not uncommon to have a delay in your symptoms. It is actually more common to have a 24 to 72 hour delay as opposed to immediate symptoms or pain. This is most likely due to the fact that it takes the body 24 to 72 hours to develop inflammation. Disc injuries may take even longer to manifest themselves. It is not uncommon for a disc injury to remain pain free and unnoticed for weeks to months.

Simply because there is little or no damage to your car does not mean that you were not injured. In fact, more than half of all whiplash injuries occur where there was little or no damage to one or both of the vehicles involved.

When we see visible damage to a car, it means that the car has absorbed much of that force and less force is transmitted to the occupant. On the other hand, if there is little or no damage to the car, the force is not absorbed

but transferred to the driver or passengers, potentially resulting in greater injury.

Diagnosis

How will my doctor identify the condition?

The diagnosis of neck problems begins with a thorough history of your condition and the involved car accident. You might be asked to fill out a questionnaire describing your neck problems. Then your doctor will ask you questions to find out when you first started having problems, what makes your symptoms better or worse, and how the symptoms affect your daily activity. Your answers will help guide the physical examination.

Your doctor will then physically examine the muscles and joints of your neck. It is important that your doctor see how your neck is aligned, how it moves, and exactly where it hurts.

Your doctor may do some simple tests to check the function of the nerves. These tests measure your arm and hand strength, check your reflexes, and help determine whether you have numbness in your arms, hands, or fingers.

The information from your medical history and physical examination will help your doctor decide which tests to order. The tests give different types of information.

Radiological Imaging

Radiological imaging tests help your doctor see the anatomy of your spine. There are many kinds of imaging tests including:

X-rays

X-rays show problems with bones, such as infection, bone tumors, or fractures. X-rays of the spine also can give your doctor information about how much degeneration has occurred in the spine, such as the amount of space in the neural foramina and between the discs.

X-rays are usually the first test ordered before any of the more specialized tests. Special

x-rays called *flexion/extension* x-rays may help to determine if there is instability between vertebrae. These x-rays are taken from the side as you bend as far forward and then as far backward as you can. Comparing the two x-rays allows the doctor to see how much motion occurs between each spinal segment.

Magnetic Resonance Imaging (MRI)

If more information is needed, your doctor may order a *magnetic resonance imaging* (MRI). The MRI machine uses magnetic waves rather than x-rays to create pictures of the cervical spine in slices. MRIs show the cervical spine vertebrae, as well as the soft tissue structures, such as the discs, joints, and nerves.

MRI scans are painless and don't require needles or dye. MRI scan has become the most common test to look at the cervical spine after x-rays have been taken.

Computed Tomography (CT)

CT scan is a special type of x-ray that lets doctors see slices of bone tissue. The machine uses a computer and x-rays to create these slices. It is used primarily when problems are suspected in the bones.

Digital Motion X-Ray (DMX)

Digital motion x-ray (DMX) is a new fluoroscopic based x-ray system designed to objectively detect and document soft tissue/ligament injury most commonly associated with whiplash injuries of the spine. DMX evaluates biomechanical relationships and abnormal movements of the cervical spine.

Specifically, DMX:

- Shows abnormal movement of vertebral bodies, facets, and other spinal elements
- Shows joint hypermobility, hypomobility, or restriction
- Shows normal or abnormal initiation of cervical motion

DMX uses digital and optic technology now available. DMX is the latest generation of *videofluoroscopy* (VF) that uses low doses of radiation. The images have improved clarity and resolution over VF and are recorded digitally on CD or DVD disc. DMX digital images can be replayed and studied on standard computer systems. DMX images are simply x-ray images taken at 30 frames per second to form a multiple radiographic array or series that can be run as a movie file to display real time motion of the joints of the body. DMX radiographic series can be paused at any location and the measurements and interpretation common to radiology can be applied to the still images. These images would be identical to plain film images if plain film radiography were performed at the same location at the same moment in motion. DMX acquires approximately 2700 images for the same amount of radiation as seven regular x-rays.

Myelogram

The *myelogram* is a special kind of x-ray test where a special dye is injected into the spinal sac. The dye shows up on an x-ray. It helps a doctor see if there is a herniated disc, pressure on the spinal cord or spinal nerves, or a spinal tumor. Before the CT scan and the MRI scan were developed, the myelogram was the only test that surgeons had to look for a herniated disc. The myelogram is still used today but not nearly as often. The myelogram is usually combined with CT scan to give more detail.

Bone Scan

A *bone scan* is a special test where radioactive tracers are injected into your blood stream. The tracers then show up on special x-rays of your neck. The tracers build up in areas where bone is undergoing a rapid repair process, such as a healing fracture or the area surrounding an infection or tumor. Usually the bone scan is used to locate the problem and other tests such as the CT scan or MRI scan are then used to look at the area in detail.

Electromyogram (EMG)

An *electromyogram* (EMG) is a special test used to determine if there are problems with any of the nerves going to the upper limbs. EMGs are usually done to see if one or more nerve roots have been pinched by a herniated disc.

During the test, small needles are placed into certain muscles that are supplied by each nerve root. If there has been a change in the function of the nerve, the muscle will send off different types of electrical signals. The EMG test reads these signals and can help determine which nerve root is involved.

Grading the Severity of Injury

The physical exam combined with the imaging studies help determine the severity or grade of the injury. There is more than one way to assign a grade to a patient's whiplash.

Here are two examples of the more commonly used models used to classify or grade whiplash injuries.

Croft Guidelines

- Grade I: Minimal – No limitation of motion, no ligamentous injury, no neurological findings
- Grade II: Slight – Slight limitation of motion, no ligamentous injury, no neurologic findings
- Grade III: Moderate – Limitation of motion, ligamentous instability, neurologic symptoms present
- Grade IV: Moderate-to-Severe--Limitation of motion, some ligamentous injury, neurological symptoms, fracture or disc derangement

Quebec Whiplash Classification

- Grade 0: No complaint or physical sign
- Grade I: Neck complaint of pain, stiffness or tenderness, no physical signs
- Grade II: Neck pain and musculoskeletal signs
- Grade III: Neck pain and neurological signs
- Grade IV: Neck pain and fracture or dislocation

Treatment

What can be done for the problem?

Nonsurgical Treatment

Whenever possible, doctors prefer to use treatments other than surgery. The first goal of these nonsurgical treatments is to ease your pain and other symptoms.

Your health care providers will work with you to improve your neck movement and strength. They will also encourage healthy body alignment and posture. These steps are designed to enable you to get back to your normal activities. Conservative care may include:

- Immobilization
- Medication
- Injection
- Physical therapy
- Chiropractic care

Immobilization

At first, your doctor may prescribe *immobilization* of the neck. Keeping the neck still for a short time can calm inflammation and pain. This might include one to two days of bed rest and the use of a soft cervical (neck) collar.

The collar is a padded ring that wraps around the neck and is held in place by a Velcro strap. A soft cervical collar may be used for the first 24 to 48 hours to help provide support and reduce pain. There is no need for a hard or rigid cervical collar unless the neck is fractured.

Soft collars should not be worn after 48 hours without a physician's approval. Studies show that prolonged immobilization can delay healing and promote disability. Wearing it longer tends to weaken the neck muscles and reduces the facet joints' sense of position called proprioception.

A cervical support pillow may offer some additional support while sleeping and helps to keep the neck in a more neutral position. Cervical pillows can be used any time by anyone for improved alignment while sleeping.

Medication

Your doctor may prescribe certain types of medication if the nerves are irritated or compressed and you have neck pain that travels down your arm (*radiculopathy*). Severe symptoms may be treated with narcotic drugs, such as codeine or morphine. But these drugs should only be used for the first few days or weeks after problems with radiculopathy start because they are addictive when used too much or improperly. Muscle relaxants may

be prescribed to calm neck muscles that are in spasm. You may be prescribed anti-inflammatory medications such as aspirin or ibuprofen.

Injection

Pain resulting from irritation of the facet joints may be alleviated with injection of an anesthetic agent similar to Novacaine such as Bupivacaine. This numbing agent both confirms the source of pain as coming from the joint and helps reduce or eliminate the pain.

Physical Therapy

Some doctors have their patients work with a physical therapist. If you require outpatient physical therapy, you will probably only need to attend therapy sessions for two to four weeks. Your rate of recovery helps determine the length of time in physical therapy. Patients with delayed recovery may need longer time in rehab.

At first, treatment is focused on easing pain and reducing inflammation. Ice and electrical stimulation treatments are commonly used to help with these goals. Electrical stimulation treatments can help calm muscle spasm and pain. Traction is a way to gently stretch the joints and muscles of the neck. It can be done using a machine with a special head halter, or the therapist can apply the traction pull by hand. Your therapist may also use massage and

other hands-on treatments to ease muscle spasm and pain.

Active treatments are added within the comfortable range of motion. The therapist will teach you specific exercises to help tone and control the muscles that stabilize the neck and upper back.

Your therapist will work with you on how to move and do activities. This form of treatment, called body mechanics, is used to help you develop new movement habits. This training helps you keep your neck in safe positions as you go about your work and daily activities. You'll learn how to keep your neck safe while you lift and carry items and as you begin to do other heavier activities.

As your condition improves, your therapist will begin tailoring your program to help prepare you to go back to work. Some patients are not able to go back to a previous job that requires heavy and strenuous tasks. Your therapist may suggest changes in job tasks that enable you to go back to your previous job. Your therapist can also provide ideas for alternate forms of work. You'll learn to do your tasks in ways that keep your neck safe and free of extra strain.

Chiropractic Care

Chiropractic care also offers another opportunity for relief of pain from a whiplash injury. Chiropractors adjust misalignments of the facet joints and vertebrae to restore the nerve signals and improve spinal health, which can impact overall physical health. Many chiropractors make these adjustments using a thrust technique called *manipulation*.

Chiropractors also take into account how nutrition, emotion, and environment affect our health. The chiropractor will assess your posture during daily activities, work, and sleep and offer you suggestions for ways to improve your day-to-day spinal alignment. You may be given some additional advice about the use of heat, cold, and exercise to help maintain the results of your chiropractic treatment.

Surgery

Most people with lingering effects from whiplash or cervical radiculopathy from whiplash get better without surgery. In rare cases, surgery may be suggested.

Rehabilitation

What should I expect after treatment?

Nonsurgical Rehabilitation

You should expect full recovery to take up to three months. Integration of rehabilitation and manipulative therapy is central in getting back to your pre-injury status.

There is a strong emphasis on keeping as active as possible, which includes incorporating manual treatments and exercise. Before your rehab program ends, your healthcare team will teach you how to maintain any improvements you've made and ways to avoid future problems.

Notes
